The Mouse and Keyboard

Mouse

- A pointing device with one or more buttons
- Important input device, but optional
- User moves physical mouse =>
  - Windows moves small bitmapped image (mouse cursor) on display
  - "Hot spot" points to a precise location on display
  - Hot spot position constantly updated by low-level logic inside Windows

Mouse Actions

- Clicking
  - Pressing and releasing a mouse button
- Dragging
  - Moving mouse while a button is pressed down
- Double Clicking
  - Clicking a button twice in succession
  - Must occur within a set period of time and with mouse cursor in approximately the same place
  - Form’s SystemInformation class has two properties that give this information:
    - int DoubleClickTime
    - Size DoubleClickSize

Information about Mouse

- More Form’s SystemInformation Properties:
  - bool MousePresent
  - int MouseButtons
  - bool MouseButtonsSwapped
  - bool MouseWheelPresent
  - int MouseWheelScrollLines

Mouse Events

- The "Control" Class defines 9 mouse events and 9 corresponding protected event handler methods
- Only one control receives mouse events
  - The one that has its Enabled and Visible properties set to true
  - If multiple controls are stacked, the enabled visible control on top receives the event
  - A Form object receives mouse events only when mouse is over its client area
    - But mouse can be “captured” by a control => it can receive mouse events when mouse is not over it

Some Basic Mouse Events and Handler Methods

- MouseDown  OnMouseDown( )
- MouseUp    OnMouseUp( )
- MouseMove  OnMouseMove( )
- MouseWheel OnMouseWheel( )
  - Delegate for each: MouseEventHandler
  - 2nd argument for each: MouseEventArgs
- Click      OnClick( )
- DoubleClick OnDoubleClick( )
  - Delegate for each: EventHandler
  - 2nd argument for each: EventArgs
MouseEventArgs Properties

- Give access to read-only data that comes with mouse event
  - int X  Horizontal position of mouse
  - int Y  Vertical position of mouse
  - MouseButtons Button
    - Enumeration possibilities:
      - None, Left, Right, Middle
      - Indicator(s) which button or buttons are currently pressed
    - Each button corresponds to a bit set
  - int Clicks
  - int Delta

Click/DoubleClick EventArgs Static Properties

- Give access to read-only data that comes with mouse Click and DoubleClick events
  - Point MousePosition
    - Result in screen coordinates
    - To convert to client area coordinates, use
      PointToClient()
  - MouseButtons MouseButtons

Sketching Example Program

- Sketch-dotNet
  - Sketching revisited
  - Using C# and the .NET Framework Class Library
  - But if window is exposed, the sketch disappears
  - Two ways to avoid this:
    1. Save the points in each sketch and redraw all line segments in response to Paint event
    2. Draw the sketch on a shadow bitmap that the program draws on while it’s drawing on the screen

Saving the Sketch points

- Could use an array:
  - Point[] apts = new Point[?????]  
  - But how big?
- Better to use a C# dynamic “ArrayList”
  - A class defined in System.Collections
    - Also has things like: Queue, Stack, SortedList, HashTable
  - To create a new ArrayList:
    - ArrayList arrlst = new ArrayList();
    - Could hold any data type(s)
  - To add elements, e.g., a Point p:
    - arrlst.Add(p);
  - Can also Insert and Remove elements
  - Accessing an element: use an indexer as for an ordinary array
    - Point p = (Point) arrlst[2];
    - Note typecast
    - Needed because indexer returns an object of type Object
  - Number of objects in an ArrayList: arrlst.Count

New Sketch-dotNet using an ArrayList

- A single run can have many sketches
  - One for each time left mouse button goes down
  - So use one ArrayList to store the points for each sketch
    - When finished (when mouse button goes up), convert to an array of Points
  - Use a second ArrayList to store the array of points for each sketch
  - Each time left mouse button goes down, start a new sketch’s ArrayList
  - Each time mouse moves with left button down, draw segment and add to current sketch’s ArrayList
  - In response to Paint event, use DrawLines(...) to draw all the line segments in each ArrayList
    - g.DrawLines(Pen pen, Point[] apt); // apt is an array of Points
  - See Sketch-dotNet-ArrayList example program
    - Here we’re really storing the drawing in a Metafile format

New Sketch-dotNet using a Shadow Bitmap

- Store the window client area as a shadow bitmap
  - Draw on it and on screen when mouse moves with its left button down
  - Draw the shadow bitmap on the screen when a Paint event occurs
  - Note that with this technique all of the information on the original points is lost
- See the Sketch-dotNet-Bitmap example program
Some Other Mouse Events and Event Handlers

- MouseEnter OnMouseEnter() – Mouse cursor has been moved onto form's client area
- MouseLeave OnMouseLeave() – Mouse cursor is no longer on top of client area
- MouseHover OnMouseHover() – Mouse cursor has entered client area and has stopped moving
  - Only happens once between MouseEnter and MouseLeave events
- Delegate for each: EventHandler
- Argument for each: EventArgs
- See Mouse-Enter-Leave-Hover example program

The Mouse Cursor

- A little bitmap on screen that indicates the location of the mouse
- Can change its appearance
- It's an object of type 'Cursor' defined in System.Windows.Forms
- Get a mouse cursor from the 'Cursors' class
  - Consists of 28 static read-only properties that return predefined objects of type 'Cursor', e.g.: Arrow, Cross, Default, Hand, Help, Beam, WaitCursor, etc.
- Some Static read/write Properties of 'Cursor' class:
  - Cursor Current
  - Point Position
  - For example to display the hourglass cursor on the form:
    - Cursor.Current = Cursors.WaitCursor;
- Some Static Cursor methods:
  - Show(); Hide();
- See MouseCursors example program

The Keyboard

- A shared resource in Windows
  - All applications receive input from the keyboard
  - But any keystroke has a single destination
    - The destination is always a ‘Control’ (e.g. a Form)
    - Object that receives a keyboard event has the ‘input focus’ – the active Form
    - Usually the topmost form
    - If form has a caption bar, it is highlighted
    - Form.ActiveForm static property returns the active form
    - this.Activate() method can be used to make a from the active form

Keys and Characters

- Think of keyboard in two ways
  - A collection of distinct physical keys
    - Code generated by a key press or release identifies the key
  - A means of generating character codes
    - Code generated identifies a character in a character set
    - Typically 8-bit ASCII code
    - In Windows, extended to 16-bit Unicode

Types of Keys

- Keyboard divided into four general groups of keys
  - Toggle keys: Pressing key changes state
    - Caps Lock, Num Lock, Scroll Lock, Insert key
  - Shift keys: Pressing key affects interpretation of other keys (‘modifier’ keys)
    - Shift, Ctrl, Alt
  - Noncharacter keys: Not associated with displayable characters; direct a program to carry out certain actions
    - Function keys, PgUp, PgDn, Home, End, Insert, Delete, Arrow keys
  - Character keys: Letters, numbers, symbol keys, spacebar, Backspace, Tab key
    - Generate ASCII/Unicode codes when pressed

Keyboard Events & Data

- KeyDown, KeyEventArtgs
  - When a key is pressed (WM_KEYDOWN)
- KeyPress, KeyPressEventArgs
  - When a character-generating key is pressed (WM_CHAR)
  - Occurs after a KeyDown event
- KeyUp, KeyEventArgs
  - When a key is released (WM_KEYUP)
- Note KeyUp/KeyDown and KeyPress event data is different
  - KeyUp/KeyDown events provide low-level information about the keystroke
  - KeyPress provides the character code
  - Keyboard combinations taken care of
KeyDown/KeyUp Events

KeyEventEventArgs Properties:
- Keys KeyCode Identifies which key
- Keys Modifiers Identifies shift states
- Keys KeyData Combines KeyCode & Modifiers
  - Keys: a huge enumeration, some examples:
    - Keys.A, Keys.z, Keys.D0 (zero key), Keys.F1, Keys.Add,
    - See Online Help on “Keys enumeration”
- bool Shift True if Shift key is pressed
- bool Alt True if Alt key is pressed
- bool Handled Set by event handler (initially false)
- int KeyValue Returns KeyData as an integer

KeyPress Event

When key(s) pressed correspond to character codes

KeyPressEventArgs Properties:
- char KeyChar Unicode/ASCII character code
- bool Handled Set by handler (initially false)

Two Example Programs

Key:
- Assembles incoming characters from keyboard into a string that is displayed on the form’s client area
  - Handles Backspace key by removing last character from string
- Handles KeyPress event

KeyArrow:
- Moves an image on the form’s client area in response to keyboard Left/Right/Up/Down arrow key presses
  - Handles KeyDown event
