

# Recursion

# Divide and Conquer

A divide-and-conquer algorithm:

- breaks down a problem into ~~two~~ *one* or more **sub-problems** of the same or related type,
- until these become **simple** enough to be solved directly.
- The solutions to the sub-problems are then combined to give a solution to the original problem.

Wikipedia [Divide-and-conquer algorithm](#)

# Fibonacci Numbers

- Definition:  $\text{fib}(0)=0$ ,  $\text{fib}(1)=1$ ,  $\text{fib}(n) = \text{fib}(n-1) + \text{fib}(n-2)$
- Result: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, ...
- Standard mathematical example for divide and conquer

```
public static int fib(int n) {  
    if (n<2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

# Fibonacci Numbers

breaks down a problem into one or more **sub-problems**  
of the same or related type

```
public static int fib(int n) {  
    if (n<2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

# Fibonacci Numbers

until these become **simple** enough to be solved directly

```
public static int fib(int n) {  
    if (n < 2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

# Fibonacci Numbers

The solutions to the sub-problems are then combined to give a solution to the original problem.

```
public static int fib(int n) {  
    if (n < 2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

# Recursion

- A *recursive method* is a method that invokes itself
- Divide recursive methods into three parts:

```
public static int fib(int n) {  
    if (n < 2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

Code before the recursive call(s)

Recursive call(s)

Code after the recursive call(s)

# Avoid Infinite Recursion

- Handle the simple case *before* the recursive call!

```
public static int fib(int n) {  
    if (n < 2) return n;  
    return fib(n-1) + fib(n-2);  
}
```

Code before the recursive call(s)

# Unfolding Recursion

# Efficiency vs. Elegance

- Recursive solutions are often elegant, but expensive
  - Lots of method invocation (expensive)
  - Big call stack required
  - May need to re-calculate values
    - fib(2) called twice in fib(4)
    - fib(1) called three times in fib(4)
- Compiler often optimizes recursion
  - Replace recursive calls with a loop
  - Allows elegance of recursion without performance penalty!

# Think Recursion!

- Can I divide the problem into simpler problems?
- Can the simplest form of the problem be solved easily?
- If so... recursion can simplify solving the problem!
